Secure Access with a Bastion Host
Set up a bastion host in a public subnet to securely access instances in a private subnet.

NAME: KEERTHIKA A

Department: AML

Introduction

In cloud environments, securing access to private instances is crucial. A **Bastion Host** (or Jump Box) is a special-purpose instance that acts as a secure gateway to access EC2 instances in a private subnet. Instead of exposing private instances directly to the internet, users connect to the Bastion Host first and then access the private instances from there.

This setup **enhances security** by limiting direct SSH access to private instances and applying strict security controls.

Overview

We will set up a **Bastion Host** in a **public subnet** that provides controlled SSH access to instances inside a **private subnet**.

What We Will Do?

1. **Create a VPC** with a **Public and Private Subnet**.
2. **Set Up a Bastion Host** in the Public Subnet.
3. **Launch a Private EC2 Instance** in the Private Subnet.
4. **Configure Secure SSH Access** via the Bastion Host.

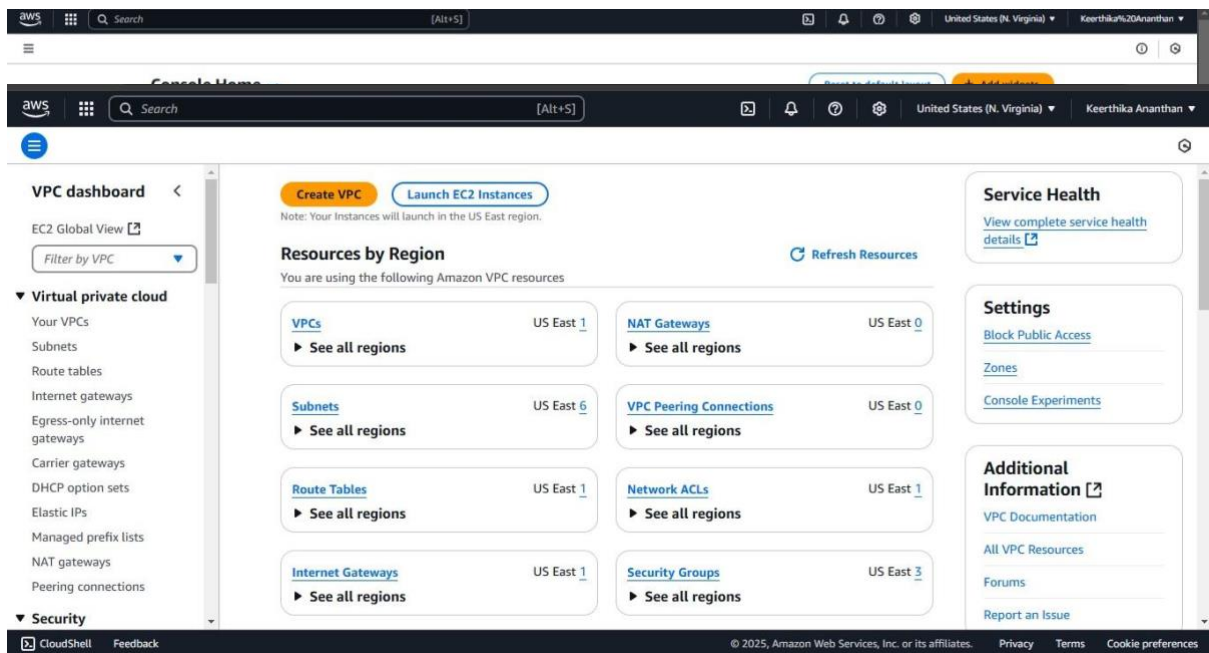

5. Enhance Security by restricting SSH access and considering AWS Systems Manager as an alternative.

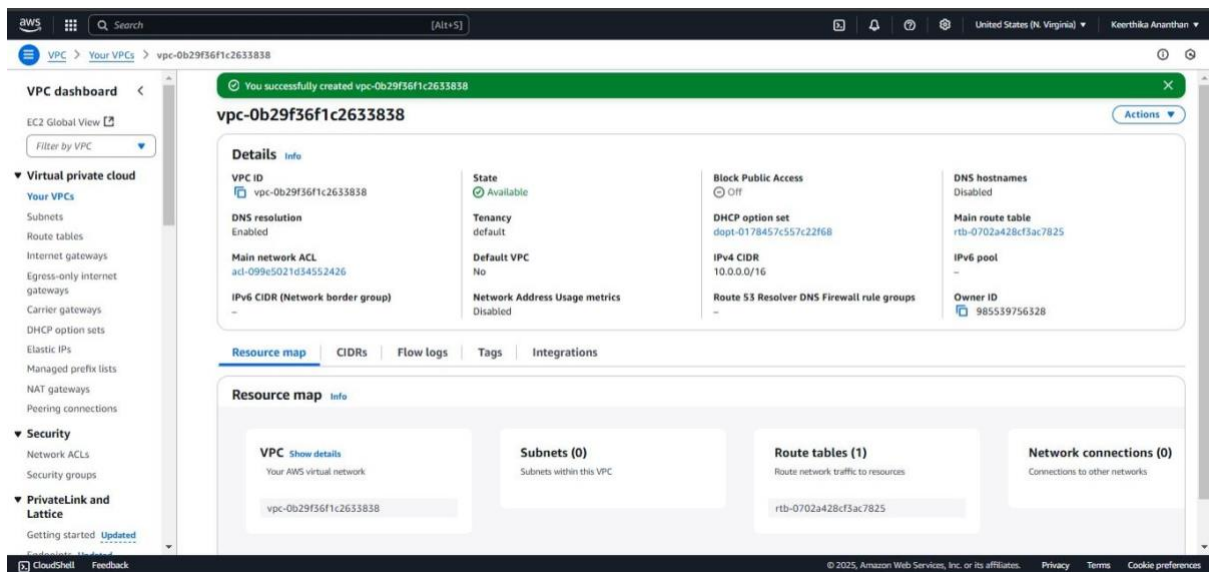

Step 1:

Create a VPC with Public and Private Subnets

1.1 Create a VPC

- Go to AWS Console → VPC Dashboard.
- Click Create VPC and name it MyVPC.
- Set IPv4 CIDR Block: 10.0.0.0/16.
- Click Create VPC.

1.2 Create a Public Subnet

- Go to **Subnets** → **Create Subnet**.
- Select **MyVPC** and set CIDR block 10.0.1.0/24.
- Enable **Auto-Assign Public IP**.

1.3 Create a Private Subnet

- Repeat the same process, but use CIDR block 10.0.2.0/24.
- **Do not enable** Auto-Assign Public IP.

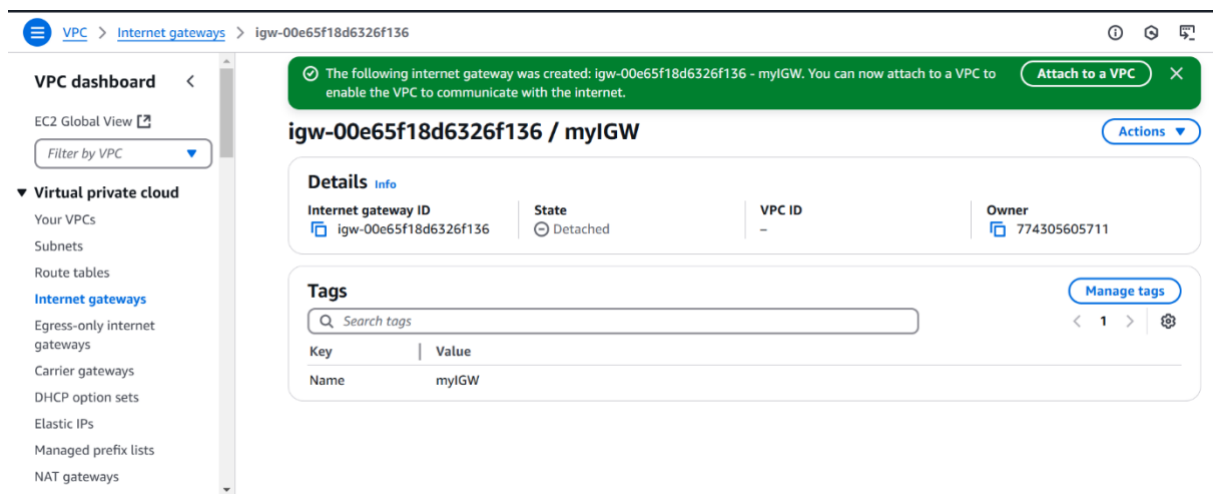

Step 2:

Configure Public Subnet for Internet Access

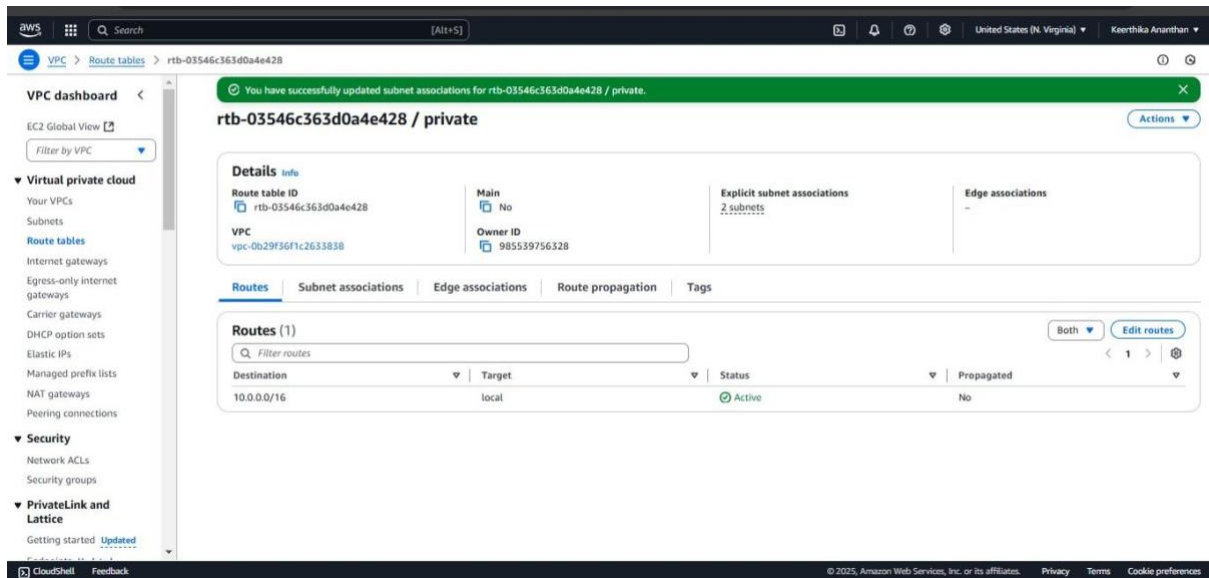

2.1 Create an Internet Gateway (IGW)

- Go to **Internet Gateways** → Click **Create Internet Gateway**.
- Name it **MyIGW**, attach it to **MyVPC**.

2.2 Update Public Route Table

- Go to **Route Tables** → **Create Route Table** → Name it **PublicRouteTable**.
- Associate it with **PublicSubnet**.
- Add a route:
 - **Destination:** 0.0.0.0/0
 - **Target:** Internet Gateway (MyIGW)

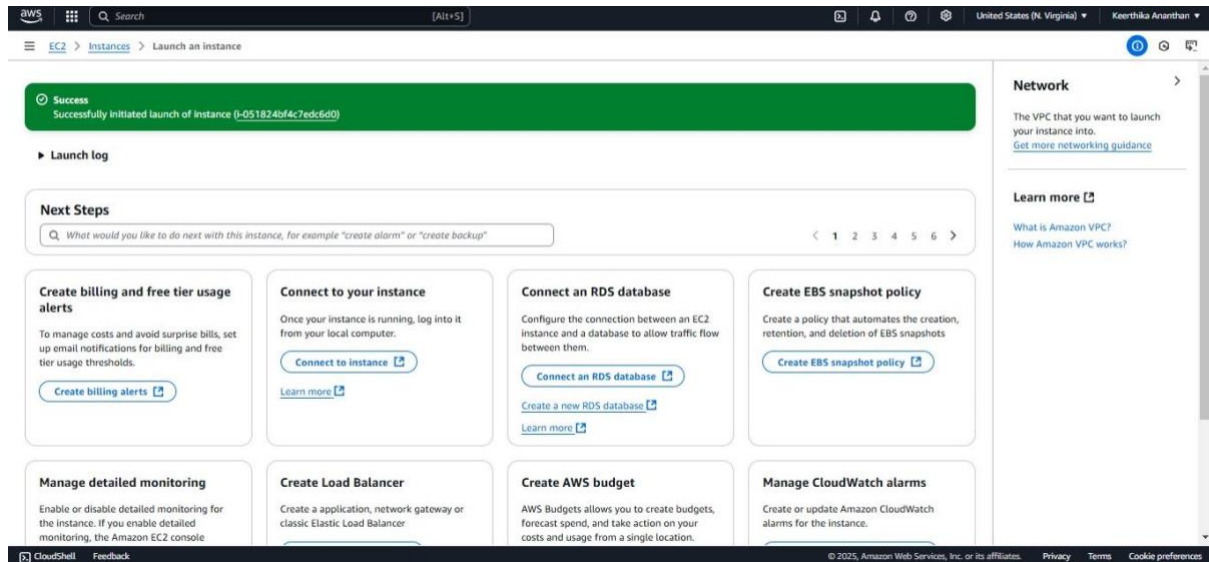

Step:3

Launch a Bastion Host (Public Subnet)

- 1.Go to EC2 Dashboard → Launch Instance.
- 2.Select Amazon Linux 2 (or Ubuntu).
- 3.Choose t2.micro (Free Tier Eligible).
- 4.Place it in PublicSubnet with Auto-Assign Public IP enabled.
- 5.Create a Security Group (BastionSG):
Allow SSH (Port 22) from Your IP
(xx.xx.xx.xx/32)
- 6.Create or use an existing key pair (e.g., bastion-key.pem).

7.click Launch

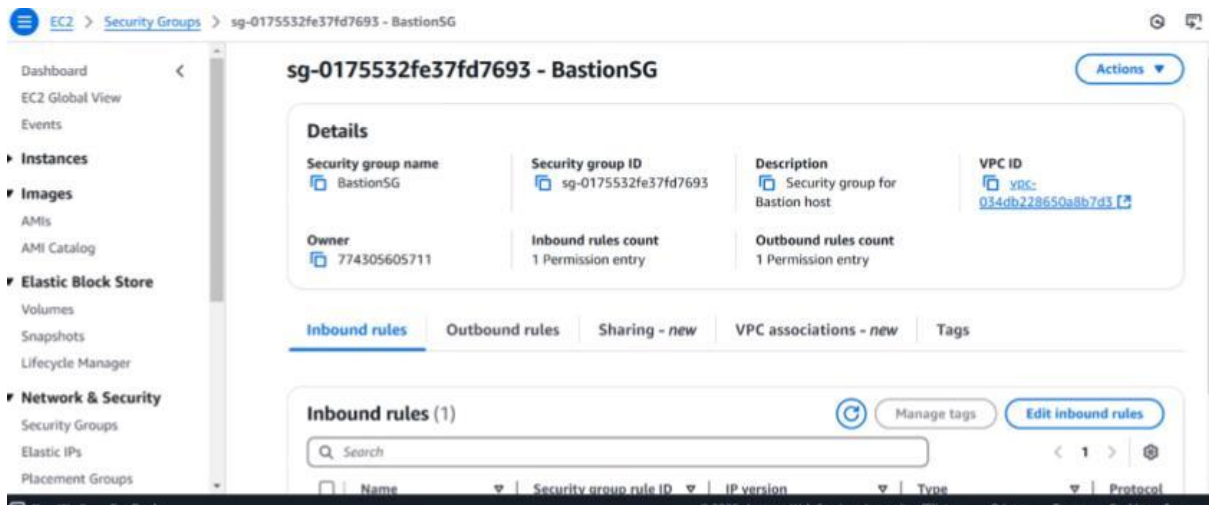

Step 4:

Launch a Private EC2 Instance

1. Go to **EC2 Dashboard** → **Launch Instance**.
2. Choose **Amazon Linux 2** (or **Ubuntu**).
3. Choose **t2.micro** and place it in **PrivateSubnet**.
4. **Disable Auto-Assign Public IP**.
5. Create a **Security Group (PrivateSG)**:

- Allow **SSH (Port 22)** only from **Bastion Host's Security Group**.
- 6. Use the same **key pair** (bastion-key.pem).
- 7. Click **Launch**.

Step 5: Connect to the Private Instance Using the Bastion Host

5.1 Connect to the Bastion Host

```
ssh -i bastion-key.pem ec2-user@<bastion-public-ip>
```

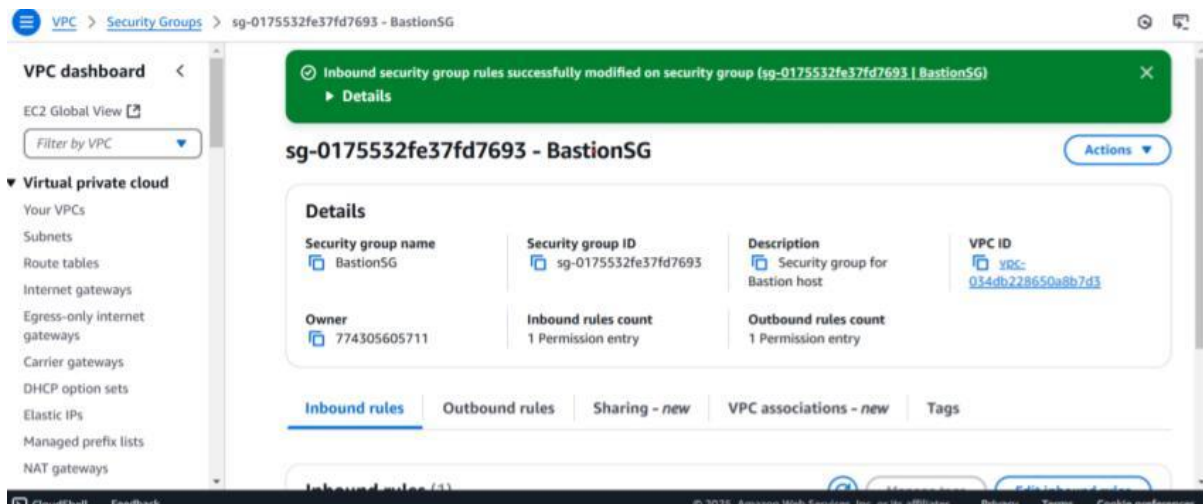

(Replace <bastion-public-ip> with the actual Bastion Host public IP.)

of your instance.)

Step 6: Secure Your Bastion Host

6.1 Restrict SSH Access

- **Go to Security Group (BastionSG) → Edit Inbound Rules.**
- **Allow SSH only from your IP address (xx.xx.xx.xx/32) instead of allowing all (0.0.0.0/0)**

6.2 Disable Password Authentication

1. Edit SSH config:

`sudo nano /etc/ssh/sshd_config`

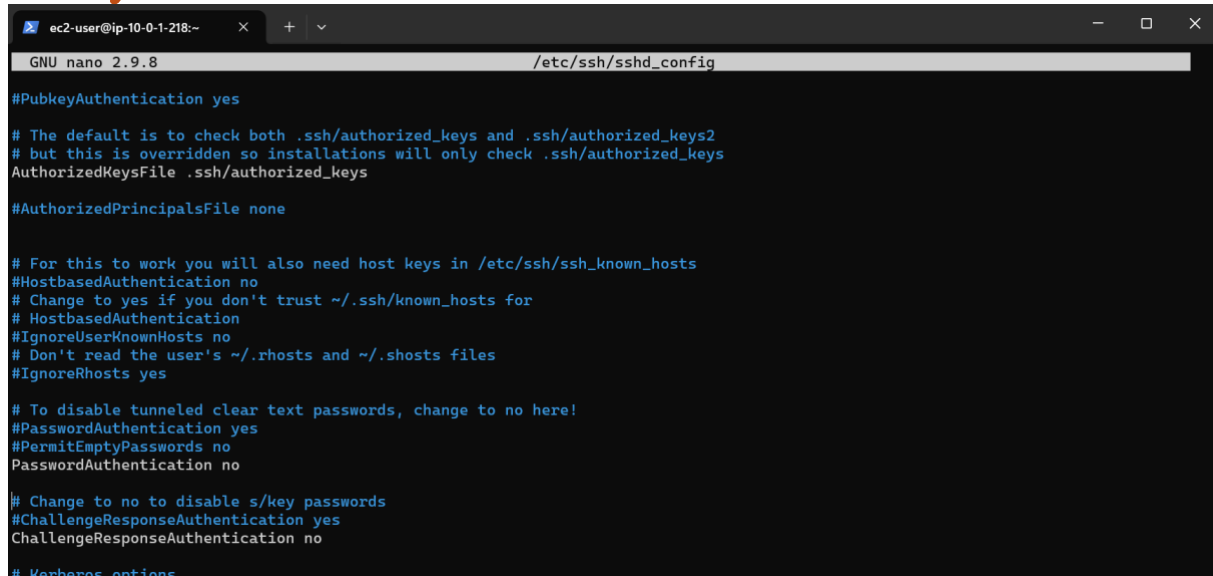

2. Find and update these lines:

`PasswordAuthentication no`

PermitRootLogin no

1.Restart SSH service:

sudo systemctl restart sshd

A screenshot of a terminal window with a dark background. The window title is 'ec2-user@ip-10-0-1-218:~'. The terminal shows the nano 2.9.8 editor editing the file /etc/ssh/sshd_config. The visible text in the editor includes: '#PubkeyAuthentication yes', '# The default is to check both .ssh/authorized_keys and .ssh/authorized_keys2', '# but this is overridden so installations will only check .ssh/authorized_keys', 'AuthorizedKeysFile .ssh/authorized_keys', '#AuthorizedPrincipalsFile none', '# For this to work you will also need host keys in /etc/ssh/ssh_known_hosts', '#HostbasedAuthentication no', '# Change to yes if you don't trust ~/.ssh/known_hosts for', '# HostbasedAuthentication', '#IgnoreUserKnownHosts no', '# Don't read the user's ~/.rhosts and ~/.shosts files', '#IgnoreRhosts yes', '# To disable tunneled clear text passwords, change to no here!', '#PasswordAuthentication yes', '#PermitEmptyPasswords no', 'PasswordAuthentication no', '# Change to no to disable s/key passwords', '#ChallengeResponseAuthentication yes', 'ChallengeResponseAuthentication no', and '# Krb5 options'.

```
ec2-user@ip-10-0-1-218:~  
GNU nano 2.9.8 /etc/ssh/sshd_config  
#PubkeyAuthentication yes  
  
# The default is to check both .ssh/authorized_keys and .ssh/authorized_keys2  
# but this is overridden so installations will only check .ssh/authorized_keys  
AuthorizedKeysFile .ssh/authorized_keys  
  
#AuthorizedPrincipalsFile none  
  
# For this to work you will also need host keys in /etc/ssh/ssh_known_hosts  
#HostbasedAuthentication no  
# Change to yes if you don't trust ~/.ssh/known_hosts for  
# HostbasedAuthentication  
#IgnoreUserKnownHosts no  
# Don't read the user's ~/.rhosts and ~/.shosts files  
#IgnoreRhosts yes  
  
# To disable tunneled clear text passwords, change to no here!  
#PasswordAuthentication yes  
#PermitEmptyPasswords no  
PasswordAuthentication no  
  
# Change to no to disable s/key passwords  
#ChallengeResponseAuthentication yes  
ChallengeResponseAuthentication no  
  
# Krb5 options
```

Step 7:

Alternative - Use AWS Systems Manager (SSM) Instead of SSH

- 1.Attach SSM Managed Policy to EC2 IAM Role (AmazonSSMManagedInstanceCore).**
- 2.Enable SSM Agent (Pre-installed on Amazon Linux & Ubuntu).**
- 3.Use AWS Systems Manager > Session Manager to connect to instances without SSH.**

Conclusion

Using a Bastion Host significantly enhances security by acting as a controlled access point to

private instances. This setup prevents direct internet exposure, enforces security group rules, and allows monitoring/logging of access.

For even better security, consider eliminating SSH and using AWS Systems Manager (SSM) Session Manager instead.
